Table of Contents

ArduinoIDE

arduino, iot, development, c programming

ArduinoIDE portable

- Download the distribution from the official webpage:

```
wget https://downloads.arduino.cc/arduino-1.8.13-linux64.tar.xz
tar xvf arduino-1.8.13-linux64.tar.xz
```

- Inside arduino-1.8.13/, create a directory named portable

```
cd arduino-1.8.13/
mkdir portable
```

- By merely existing, this `portable` directory modiffies the base behaviour of the ArduinoIDE environment. From now on, all the libraries, compilers, utilities, and conffiguration files are always contained within the portable folder.

```
cd arduino-1.8.13/
./arduino
```

ArduinoIDE with external Editor

- Go to settings and mark the `Use External Editor` option.
- Now you can edit the sketch files with your favourite editor and save.
- When you're done with editing, use ArduinoIDE `Upload`and Serial Console normally.

ArduinoIDE terminal compile and program board

- You can compile and program the board using ArduinoIDE from the terminal:

```
./arduino
    --port /dev/ttyUSB0
    --board Arrow:samd:SmartEverything_Fox_native
    --preserve-temp-files --pref build.path=/home/jsanchez/tmp/arduinobuild
    --verify || OR || --upload
    ./MYSKETCH.ino
```

- `--port` must be set to your serial device port.
- `--board` must be set to your board model (more on this next).
- `--preserve-temp-files` tells the compiler to build only the updated files instead of all the

code.
    - This is a HUGE time saver!.
    - Must specify with –pref build.path the directory to contain all the temporary object files. This directory can be safely be deleted later.
- `--verify` only compiles the code without uploading it to the board (nice for debugging).
- `--upload` compiles and uploads the code to the board.

Don't forget the `./` in front of your sketch name!!

Finding the board name

```
./arduino
  --port /dev/ttyUSB0
  --board Arrow:samd:SmartEverything_Fox_native
  --preserve-temp-files --pref build.path=/home/jsanchez/tmp/arduinobuild
  --verify || OR || --upload
  ./MYSKETCH.ino
```

- `--board` must be set to your board model.
- You can find several boards.txt files in your source tree.

```
hardware/arduino/avr/boards.txt
portable/packages/Arrow/hardware/samd/2.1.0/boards.txt
portable/packages/arduino/hardware/samd/1.6.18/boards.txt
```

You can build the board following the dir names and within the boards.txt file itself:
`SmartEverything_Fox_native.name=SmartEverything Fox (Native USB Port)`

ArduinoIDE modular code

- Besides your `.ino` file, you can place additional source files within your sketch folder.
- These will be compiled and linked implicitly by the ArduinoIDE toolchain.
- However, don't forget to do apply the correct C/C++ modular code practices!! i.e. `#include`, `extern`, etc.
- Note how the files are listed as TABS in the ArduinoIDE interface.

ArduinoIDE Debug PRINT

- Print function calls can be controlled across a whole `.c` file without rewriting code.
- This enables us to switch the debug PRINT on/off with a simple macro definition `#define DEBUG`.
- This is implemented in some way or another in difierent projects. It is a very widespread practice.
- Copy this block in your C file.

```
#ifdef DEBUG

  #define PRINT(...) Serial.print(__VA_ARGS__)
  #define PRINTLN(...) Serial.println(__VA_ARGS__)
  #define PRINT_ARRAY(add, len) \
  do { \
    int i; \
    for (i = 0 ; i < (len) ; i++) { \
      Serial.print((unsigned int)((uint8_t*)(add))[i], HEX); \
    } \
    Serial.println(); \
  } while(0)

#else /* DEBUG */

  #define PRINT(...)
  #define PRINTLN(...)
  #define PRINT_ARRAY(add, len)

#endif /* DEBUG */
```

- Then, write conditional print sentences as `PRINT(var)`.
- Additionally, the `PRINT ARRAY(address, len)` function simply prints in HEX an array passed

as an argument.
- **NOTE** to activate the conditional debut pring, `#define DEBUG` must be writen **before** the previous code block.
    - Alternatively, it can be defined with a compiler CFLAG environment variable.

      Use example:

```
uint8_t foo[255];
int bar = 7;
...
PRINTLN(bar);
PRINT_ARRAY(foo, sizeof(foo))
// These prints only if the DEBUG macro was defined.
7
EE FF 01 25 ...
```

ArduinoIDE alternative serial consoles

- ArduinoIDE comes with an embedded serial console.
- Alternatively you can use a serial console like picocom, but you must set it to the right parameters.

```
picocom

  -g "logs/serial_console_log.txt" # Save the consolo text in a log file
  -r                               # NO-reset - avoid reseting the device
  -b 115200                        # Baudrate - MUST MATCH ARDUINOIDE!
  --omap crcrlf                    # Mapping of EOL characters
  /dev/ttyACM0
```

- Exit Picocom with `Ctrl+A`, `Ctrl+X`.

Meter código C en Arduino

Se pueden meter archivos `.c` y sus respectivos `.h` en el mismo directorio que el sketch:

Fuente: https://forum.arduino.cc/index.php?topic=45003.0

C++, which the Arduino is programmed in, performs name-mangling. C, which your external functions are written in, does not.

Name-mangling means that the actual function that gets called is called using a name that is composed of the class name, function name, and argument type names.

In order to call a C function from a C++ function, the compiler needs to know that it should use C

calling syntax, not C++ calling syntax.

In the header file, before any function declarations, add:

```
#ifdef __cplusplus
extern "C" {
#endif
```

After all function declarations, add:

```
#ifdef __cplusplus
}
#endif
```

This will allow the C functions to be called from C++.

IMPORTANT Make sure that the files that you are compiling appear in the ArduinoIDE as tabs. If not, the compiler does not recognize them. Always rename your `.c` files to `.cpp`.

Code Footprint

Reducir el tamaño de los firmwares

Por defecto, arduino le pasa al compilador el Flag `-g`, este flat añade a los archivos `.o` varios campos de depuración, que son listados en el `.map` como `.debug_info`, `.debug_range`, etc. Este código incrementa considerablemente el tamaño del firmware.

Para eliminar el código de depuración de los archivos objeto, editar el archivo `platform.txt` y quitar la opción `-g` de todos los flags de compilación.

- Los flags de compilación se encuentran en el archivo `platform.txt`, son líneas con el nombre `compiler`.

  E.g.:

```
arduino-1.8.0/portable/packages/Arrow/hardware/samd/2.1.0/platform.txt
```

Luego compilar los firmwares respectivos, abrir el directorio de compilación y utilizar el script:

```
python3 ~/bin/analyze_map.py coap_eap_integration.ino.map
```

Los archivos que pertenecen a cada una de las partes del código están listados en el readme de cada firmware.

Ejemplo de lo que estamos hablando:

```
Coap
